

A new approach to film processing

The E.D.L. DM-11
Spray Processor—
48 sec from camera
to projector at a rate of
52 ft/min using DuPont
930 Reversal Pan

This machine was designed and built for the Delaware Steeplechase and Race Association by the E.D.L. film process machine engineers, designers and builders of all types of process machines for the quality-minded film producer and laboratory. We offer services in the design and construction of magnetic recorders, video recorders, special-purpose printers and high-production film process machines for all film processes. We invite a statement of your problems.

the E.D.L. Company

5929 E. Dunes Highway, Gary, Ind.

Professional Junior Tripod

—used by more professional cameramen
than any other tripod in the world.

Shown with friction type head which handles all 16mm cameras, with or without motor. Also 35mm B & H Eyemo, DeVry. Interchangeable with gear drive head. "Baby" tripod base and "Hi-Hat" also available.

If you're a professional—you need
"Professional Junior" Tripod. See it today.

SALES • SERVICE • RENTALS

- *9.5mm Lenses in 16mm C mount. 18.5mm (extreme wide angle-flat field) Lenses available in mounts for all 35 mm Motion Picture Cameras.
- *PHOTO RESEARCH Color Temperature Meters. *Electric Footage Timers
- *Neumade and Hollywood Film Company cutting room equipment.
- *Griswold & B.&H. Hot Splicers. *DOLLIES—Bardwell-McAlister, Mole Richardson, Century and Colortran Lighting Equipment.

Complete line of 16mm and 35mm Cameras

SPLICES NOT HOLDING? Try Jefrona all-purpose cement.
Send for FREE sample.

To measure lenses objectively, an electronic instrument has been developed by the Radio Corp. of America, according to an announcement by M. C. Batsel, Chief Engineer of RCA Engineering Products Div., Camden, N.J. The lens-tester is described as a major advance in the optical sciences, in that it will introduce accuracy, speed and economy in pre-rating lenses of all types. It will enable the selection of lenses by specific grade, with the exact characteristics for given applications. The electronic lens-tester resulted from initial research conducted by Otto H. Schade, who has pioneered in the development of universal ratings and allied test equipment — see, for instance, Dr. Schade's article in this issue.

Heretofore, the quality of any lens, with

regard to sharpness, contrast and gradation, has been determined solely by visual tests. The lens-tester has been designed to enable lens manufacturers and users to determine quickly the lens' response characteristics and apply them against mathematical optimums. Many significant properties of an image depend upon the characteristics of its star image — the image of a point source of light. The star image of an optical "circuit" has been demonstrated to be the counterpart of the impulse response of an electrical circuit. Accordingly, the mathematical relationship of electrical impulse response, frequency responses and edge transitions can be applied to compute counterpart properties of optical star images.

Major components of the developmental RCA lens-tester include a special test drum, a microscope, a multiplier phototube and an oscilloscope. The test drum has nine groups of high contrast black and white lines of different widths, ranging from 3/in. for the coarse group to 200/in. for the finest group. The black lines correspond to 3 to 200 TV lines/mm in the image.

To obtain the square-wave flux response of a given lens, it is made to view the test drum, which is revolved by a synchronous motor. The lens is also rotated, about its transverse axis, to test its performance off axis. The lens image of the test drum is then scanned by the multiplier phototube through a narrow slit. For a theoretically perfect lens, the contrast between black and white lines, as measured by the phototube, would be modified only by diffraction effects. With a practical lens, the contrast deteriorates as the line width decreases due to the combined effects of diffraction and aberrations, or defects. The line at which
